DAY 6 · TWEET 1 OF 9

Tweet 1 - Hook

Intent: Open with the combined Day 6 answer: rebounding really matters when teams win both ends of the glass.

VISUAL SPEC

- Title: Glass-control archetypes versus overperformance
- X-axis: Mean overperformance vs exact seed
- Y-axis: Rebounding archetype
- Must show: owning both ends beats one-sided rebounding

REVIEW NOTES

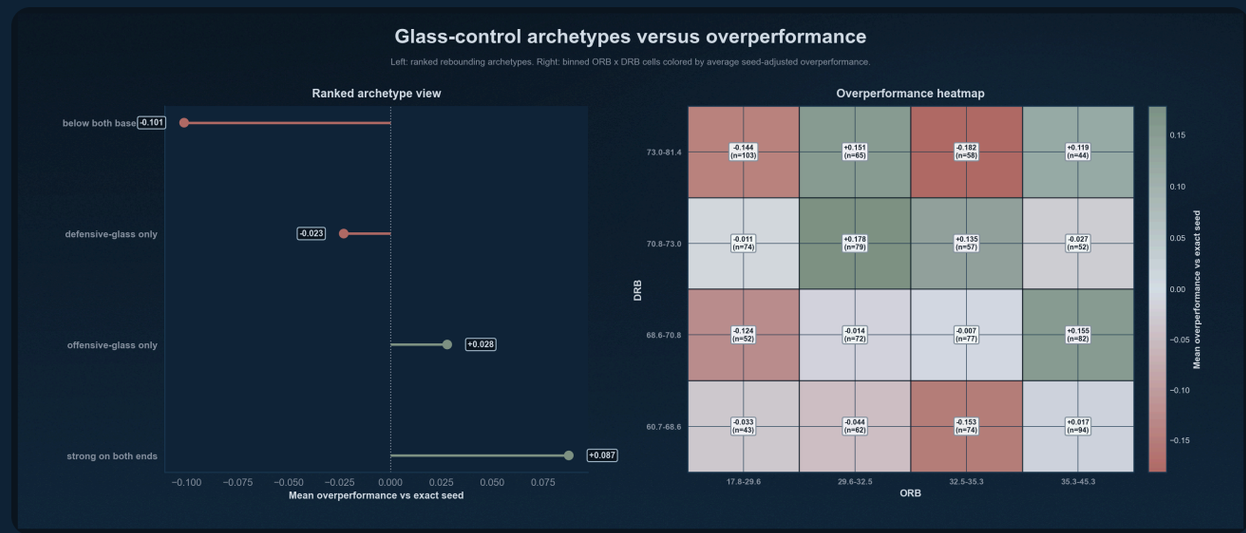

- This should feel immediate, not technical.
- The hook is that balanced glass control is the real March edge.

DRAFT COPY

Day 6 is rebounding, and the cleanest read is simple:

winning both ends of the glass matters.

Teams that were above their seed baseline in both offensive and defensive rebounding beat expectation by +0.087.
Teams below both were at -0.101.

figures/rebounding_thread/1_rebounding_hook.png

DAY 6 · TWEET 2 OF 9

Tweet 2 - Metrics

Intent: Define the Day 6 metric stack in plain language.

VISUAL SPEC

- Title: Text-only framing tweet
- Must show: one role for ORB and one role for DRB

REVIEW NOTES

- Keep the wording plain.
- Do not lapse into raw stat-code jargon.

DRAFT COPY

For Day 6, I kept it simple:

ORB = how well you extend possessions on offense.
DRB = how well you finish possessions on defense.

Question: does owning the glass actually help teams beat seed expectation in March?

Text-only slide

DAY 6 · TWEET 3 OF 9

Tweet 3 - Context

Intent: Show how the tournament rebounding environment changed over time before making a bracket claim.

VISUAL SPEC

- Title: Rebounding context over time
- X-axis: Season
- Y-axis: Tournament field average
- Must show: ORB and DRB as separate context lines

REVIEW NOTES

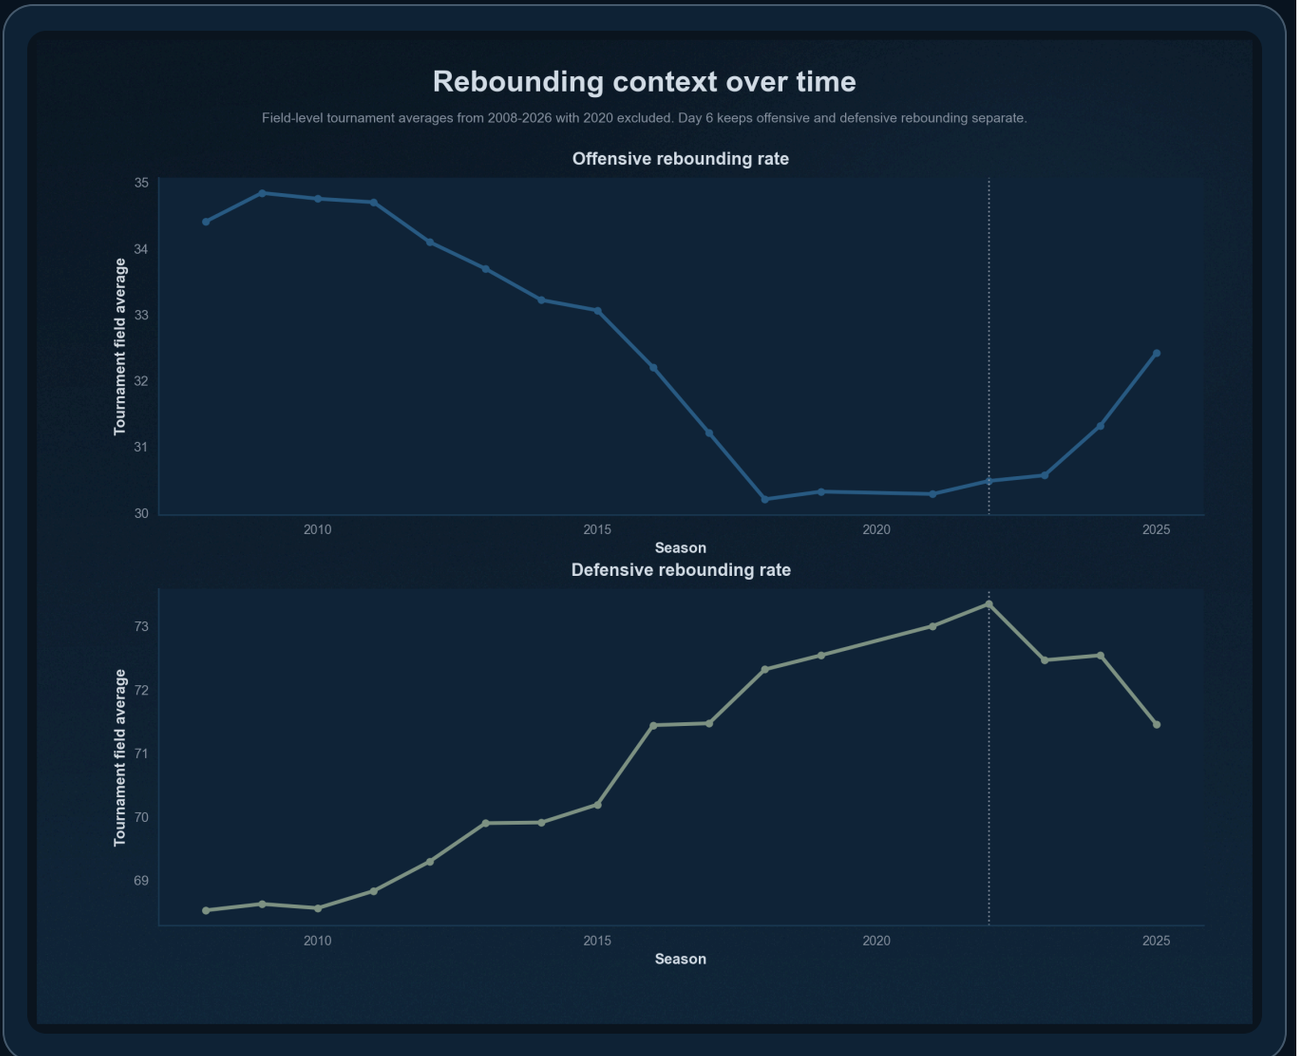

- This should explain the environment, not the result.

DRAFT COPY

The tournament field has changed.

Offensive rebounding has drifted down over time.
Defensive rebounding has climbed.

That matters because the Day 6 edge now lives in a different possession environment than it did in 2008.

figures/rebounding_context_over_time.png

DAY 6 · TWEET 4 OF 9

Tweet 4 - Pooled Relationship

Intent: Show the pooled relationship to overperformance after controlling for seed baseline.

VISUAL SPEC

- Title: Rebounding versus March overperformance
- X-axis: Better or worse than seed baseline
- Y-axis: Mean overperformance vs exact seed
- Must show: clear split for ORB and DRB

REVIEW NOTES

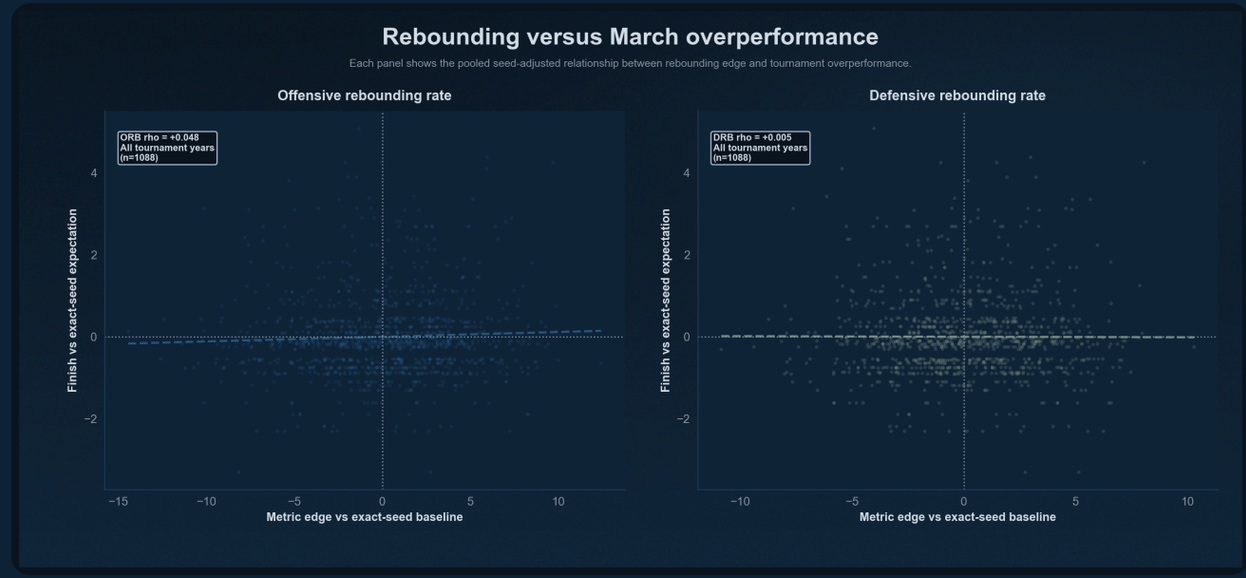

- This is the first direct answer slide.

DRAFT COPY

The pooled answer is offense first.

Teams that offensive rebounded better than their seed baseline were +0.051 in overperformance.
Teams worse than baseline were -0.054.

The defensive-rebounding split is much smaller.

figures/rebounding_vs_finish_pooled.png

DAY 6 · TWEET 5 OF 9

Tweet 5 - By Year

Intent: Check whether the Day 6 signal was stable or streaky by tournament year.

VISUAL SPEC

- Title: Rebounding signal by tournament year
- X-axis: Season
- Y-axis: Seed-adjusted Spearman rho
- Must show: one panel per side of the glass

REVIEW NOTES

- Useful for showing noise versus stability.

DRAFT COPY

The year-by-year read is not perfectly smooth.

But the offensive-rebounding signal shows up more often than the defensive one, which is exactly why Day 6 should not start with a vague total-rebounding story.

figures/rebounding_by_year.png

DAY 6 · TWEET 6 OF 9

Tweet 6 - Seed Bands

Intent: Localize where the rebounding edge actually matters in the bracket.

VISUAL SPEC

- Title: Where rebounding matters by seed band
- X-axis: Seed band
- Y-axis: Seed-band Spearman rho
- Must show: ORB and DRB side by side

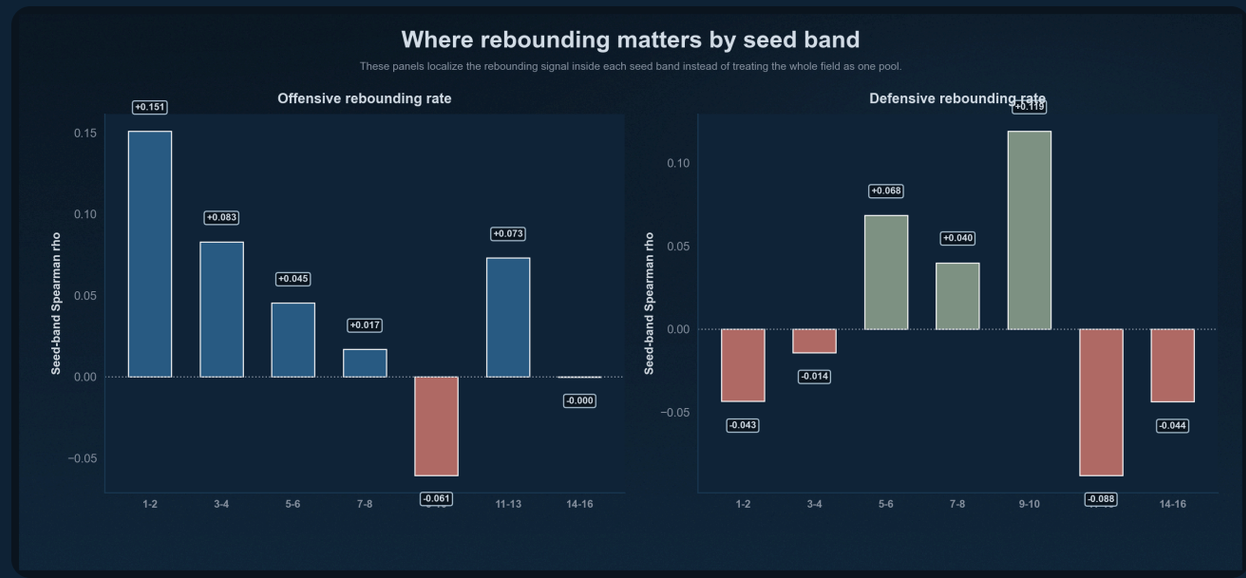

REVIEW NOTES

- This should answer where to care the most.

DRAFT COPY

Rebounding is not equally useful everywhere in the bracket.

This is the Day 6 localization slide: where ORB helps most, where DRB matters more, and where the glass barely moves the March outcome.

figures/rebounding_vs_finish_by_seed_group.png

DAY 6 · TWEET 7 OF 9

Tweet 7 - Archetypes

Intent: Combine the two rebounding sides into one archetype view.

VISUAL SPEC

- Title: Glass-control archetypes versus overperformance
- X-axis: Mean overperformance vs exact seed
- Y-axis: Rebounding archetype
- Must show: the balanced profile wins

REVIEW NOTES

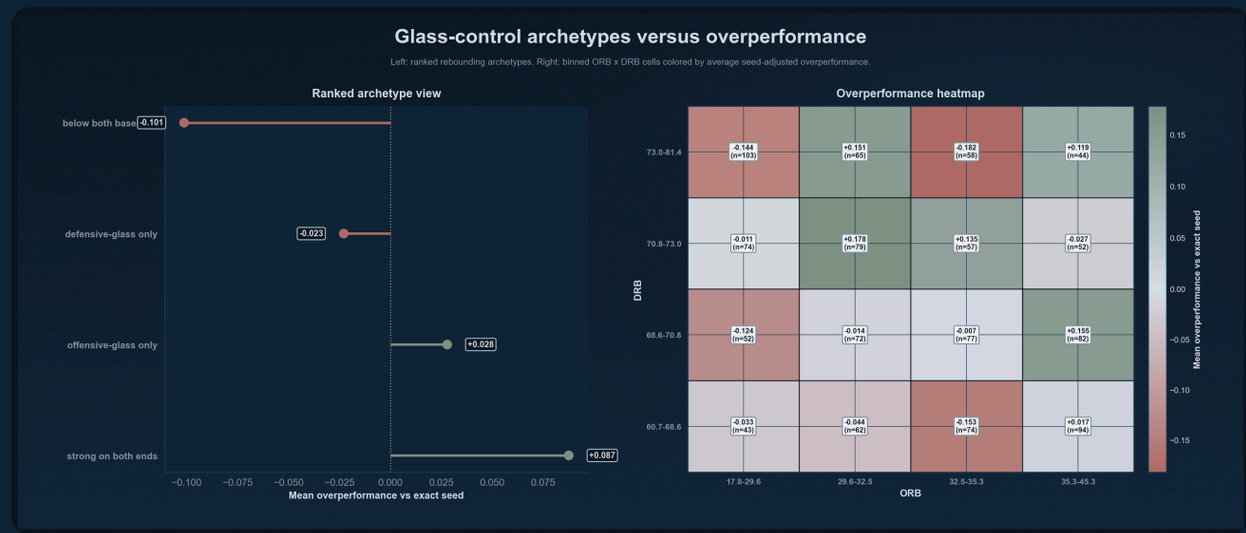

- This is still one of the strongest Day 6 slides.

DRAFT COPY

This is the Day 6 synthesis.

Strong on both ends of the glass: +0.087.
Below both baselines: -0.101.

One-sided rebounding is not worthless, but the real edge is possession control on both ends.

figures/rebounding_archetypes_vs_overperformance.png

DAY 6 · TWEET 8 OF 9

Tweet 8 - 2026 Field

Intent: Apply the Day 6 framework directly to the 2026 field with logos and former champs.

VISUAL SPEC

- Title: Projected 2026 rebounding profiles
- X-axis: Offensive rebounding rate (ORB)
- Y-axis: Defensive rebounding rate (DRB)
- Must show: both sides of the glass in one raw-metric map

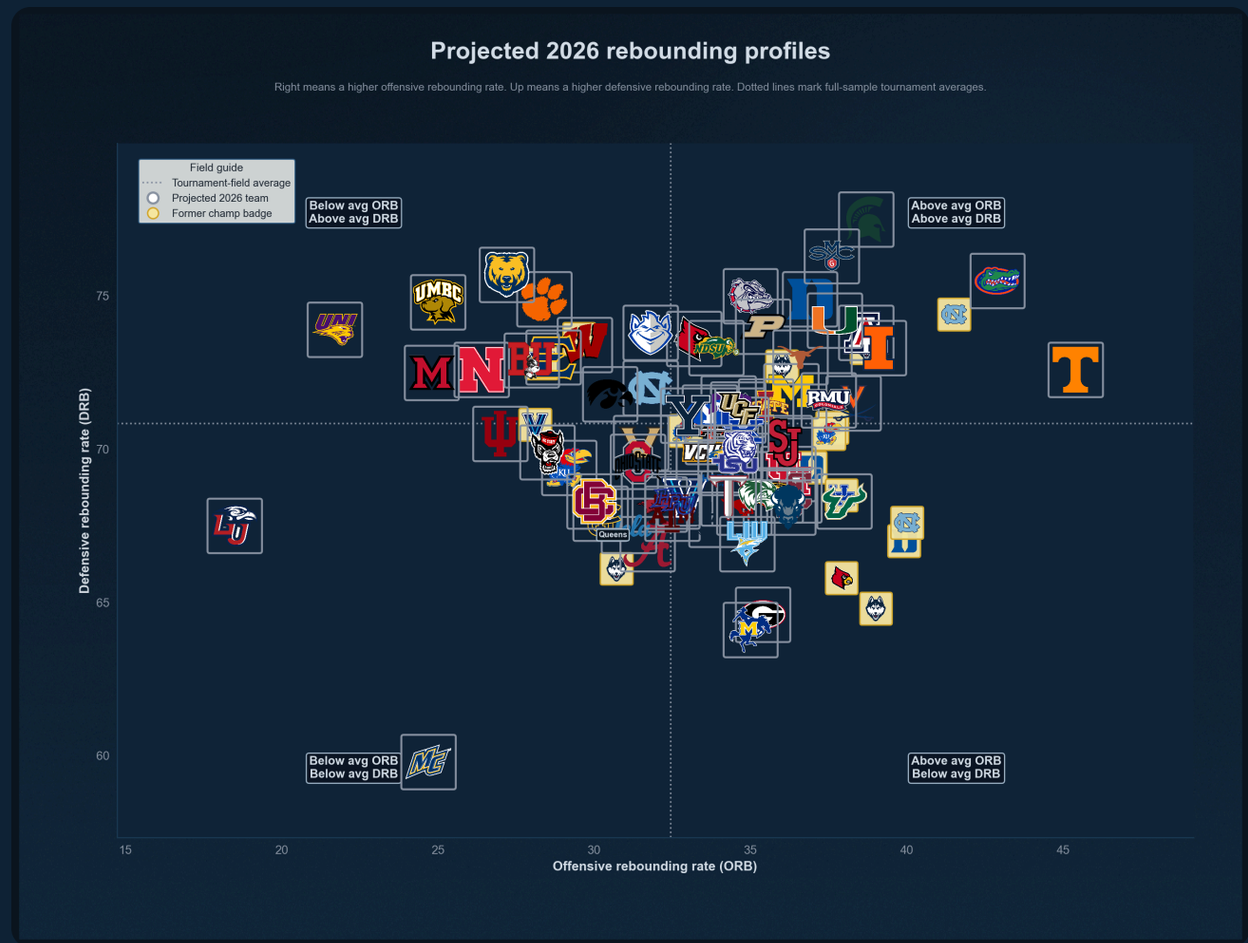

REVIEW NOTES

- This is the practical bracket-use slide.

DRAFT COPY

Now apply it to 2026.

Which teams already live in the strongest raw rebounding territory?
Which teams only control one side of the glass?
And which teams look exposed on both ends?

figures/rebounding_2026_profile_map.png

DAY 6 · TWEET 9 OF 9

Tweet 9 - Close

Intent: Wrap the Day 6 read in one usable bracket takeaway.

VISUAL SPEC

- Title: Text-only close
- Must show: offensive rebounding matters, but balanced glass control matters most

REVIEW NOTES

- Close with the usable bracket rule.

DRAFT COPY

Day 6 takeaway:

Rebounding does help in March, but not as one vague category.

Offensive rebounding is the cleaner standalone edge.
The best overall profile is still owning both ends of the glass.

That is the version worth carrying into the bracket.
